

Emissions Inventory Help Sheet for Bakeries

What do I need to report?

Bakeries need to report air pollution emissions from the burning of fuels in ovens and boilers, as well as from the production of baked yeast products, which emit ethanol, a **volatile organic compound (VOC)**. VOC emitted from baking should be reported on *Evaporative Process Forms*. Fuel-burning processes such as natural gas ovens, boilers and water heaters, need to be reported on *General Process Forms*. Burning fuel emits CO, NO_x, PM₁₀, SO_x, and VOC. See the “Instructions for Reporting 2005 Annual Air Pollution Emissions” for more information and examples of completed forms.

How do I fill out the Evaporative Process and General Process Forms?

- For bakery products, use a separate Evaporative Process Form for each oven which bakes yeast products. List each yeast product baked in that oven on its own line as a “Material Type” and give each a Process ID number. If Process IDs are not pre-printed on your forms, assign a different Process ID number for each material type.
- For natural gas consumption, use one General Process Form for each category of equipment rating in use: “< 10,000,000 Btu/hr” or “10–100,000,000 Btu/hr.”
- “Process Type/Description” should include basic process information such as:
Example for an Evaporative Process Form: “Bread products baked in oven #1.”
Example for a General Process Form: “2 ovens and 1 boiler, each <10,000,000 Btu/hr.”
- Tier Codes: – on the Evaporative Process Form, use 070103 (food products, bakeries).
– on the General Process Form, use 020301 (industrial external fuel combustion, natural gas).
- On the Evaporative Process Form, “Material Type” (column 8) is the yeast product name, formula or recipe name as reported on the Baked Yeast Products Emission Factor Calculation Form, on the back of this Help Sheet. Submit the Baked Yeast Products Emission Factor Calculation Form with your report. On the General Process Form, “Emissions based on” (line 9) is the name of the fuel used, which is typically natural gas.

How do I determine the emission factors for my baked yeast products?

The emission factor is the number used to calculate pounds of pollutant (VOC) emitted from pounds of yeast product baked. See the Baked Yeast Products Emission Factor Calculation Form on the reverse for complete instructions. Attach this form or a spreadsheet equivalent to your report.

To calculate emissions from baking: Report in column 9 of the Evaporative Process Form the number of pounds of each yeast product that was baked during the year. Then multiply the number of pounds of product by the emission factor, and enter the result in column 15.

How do I determine the emission factors for my natural gas oven or boiler?

The table below shows the SCC Codes and emission factors for the most common external combustion equipment, which includes ovens, boilers and hot water heaters. The figures below assume that only natural gas is used. If you use another fuel, please call (602) 506-6790 for further guidance.

Natural Gas Equipment Rating	SCC	Pollutant and Emission Factor (in lbs/MMCF)					
		CO	NO _x	PM ₁₀	SO _x	VOC	Lead
10–100 MM Btu/Hr	10200602	84	100	7.6	0.6	5.5	0.0005
<10 MM Btu/Hr	10200603	84	100	7.6	0.6	5.5	n/a

To calculate emissions from natural gas ovens and boilers: On the General Process Form, report on line 11 the total number of natural gas therms used during the report year. Write the word “therms” on line 13. Show the conversion factor of **0.0000952** on line 14, to convert therms to million cubic feet (MMCF). In the table, write each pollutant on its own line in column 15 and its emission factor in column 16. Write the unit “lb/MMCF” in column 17. Calculate emissions of each pollutant by multiplying the number of therms times the conversion factor times the pollutant emission factor, and enter the result in column 25. A detailed example can be seen in the Help Sheet titled “Emissions Inventory Example: Natural Gas Boilers and Heating Equipment.”
